***Abstract*—This report presents the implementation and rigorous evaluation of two fundamental deep learning tasks. Task 1 investigates Deep Belief Networks (DBNs) for customer churn prediction, detailing theoretical foundations, layer-wise generative pre-training, and comparing its inductive biases against Convolutional Neural Networks (CNNs). Task 2 focuses on generative Visual Question Answering (VQA) using the A-OKVQA dataset. We propose a multimodal architecture utilizing a pre-trained ResNet-50 for spatial image feature extraction, a 2-layer LSTM with pre-trained GloVe embeddings for question encoding, and an autoregressive LSTM-decoder. Extensive experiments evaluate architectural variants across multiple random seeds, specifically analyzing the critical theoretical and empirical impacts of Dual Attention mechanisms, Residual Learning, and Penalized Beam Search on sequence generation capabilities.**

***Index Terms*—Deep Learning, Deep Belief Network, Visual Question Answering, A-OKVQA, Transfer Learning, ResNet-50, CNN, LSTM, Dual Attention, Beam Search.**

I. Task 1: Deep Belief Networks (DBN)

A. Theoretical Foundations of Deep Belief Networks for Churn Prediction

1) Mathematical Formulation as a Generative Model: The Deep Belief Network (DBN) is formally defined as a probabilistic generative model composed of L layers of latent variables $\mathbf{h}^{(1)}, \dots, \mathbf{h}^{(L)}$. Unlike simple feedforward networks, the DBN is a hybrid graphical model. The joint distribution $P(\mathbf{v}, \mathbf{h}^{(1)}, \dots, \mathbf{h}^{(L)})$ factorizes as:

$$P(\mathbf{v}, \mathbf{h}^{(1)}, \dots) = P(\mathbf{h}^{(L-1)}, \mathbf{h}^{(L)}) \prod_{l=0}^{L-2} P(\mathbf{h}^{(l)} | \mathbf{h}^{(l+1)}) \qquad (1)$$

where $\mathbf{h}^{(0)} = \mathbf{v}$ denotes the visible layer. Crucially:

- The top two layers form an undirected **Restricted Boltzmann Machine (RBM)**, defined by the joint distribution $P(\mathbf{h}^{(L-1)}, \mathbf{h}^{(L)})$.
- The lower layers constitute a **Directed Sigmoid Belief Network**, where conditional distributions $P(\mathbf{h}^{(l)} | \mathbf{h}^{(l+1)})$ propagate generative probabilities top-down.

This hierarchical decomposition allows the DBN to first learn a *generative model* of the customer data distribution $P(\mathbf{v})$ through unsupervised pre-trainingcapturing everything from low-level statistical correlations to high-level behavioral patterns. Subsequently, this robust generative prior can be fine-tuned for *discriminative tasks* like churn classification.

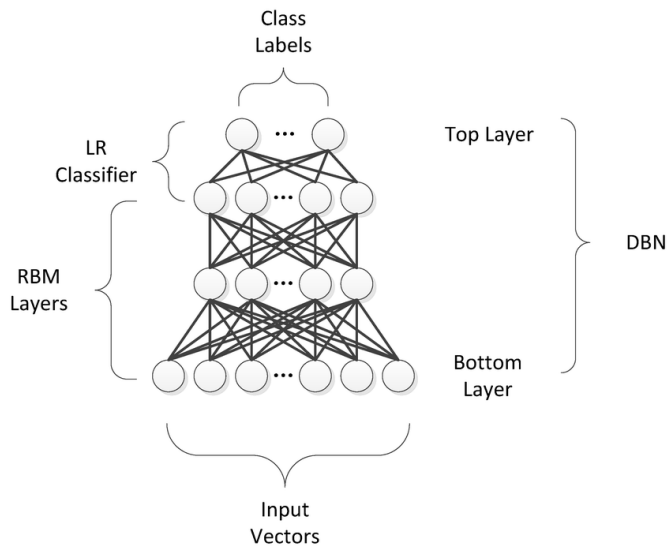

Fig. 1. Hybrid architecture of a Deep Belief Network (DBN) applied to churn prediction. The top two layers form an undirected RBM, while the connections to lower layers are directed.

2) Restricted Boltzmann Machine (RBM): The RBM serves as the fundamental building block for layer-wise learning. It is an Energy-Based Model (EBM) defined over a bipartite graph of visible units $\mathbf{v} \in \mathbb{R}^D$ and hidden units $\mathbf{h} \in \{0,1\}^K$.

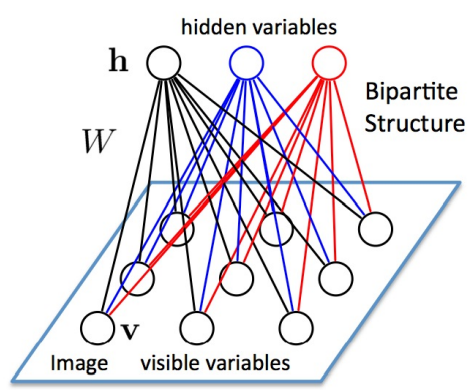

Fig. 2. Bipartite graph structure of a Restricted Boltzmann Machine (RBM). The lack of intra-layer connections ensures conditional independence.

a) Energy Function and Canonical Distribution: For real-valued input data, we employ the **Gaussian-Bernoulli RBM**. The energy function $E(\mathbf{v},\mathbf{h})$ is defined as:

$$E(\mathbf{v},\mathbf{h}) = \sum_{i=1}^{D} \frac{(v_i - a_i)^2}{2\sigma_i^2} - \sum_{j=1}^{K} b_j h_j - \sum_{i=1}^{D}\sum_{j=1}^{K} \frac{v_i}{\sigma_i} h_j w_{ij} \quad (2)$$

b) Free Energy and Churn Likelihood: A critical concept for our application is the **Free Energy** $F(\mathbf{v})$:

$$F(\mathbf{v}) = \sum_{i} \frac{(v_i - a_i)^2}{2} - \sum_{j} \ln\left(1 + e^{b_j + \sum_i v_i w_{ij}}\right) \quad (3)$$

A high Free Energy $F(\mathbf{v})$ corresponds to a low probability event, providing a theoretically grounded metric for **churn risk scoring**.

3) Contrastive Divergence: Optimization Objective: Exact maximum likelihood learning in RBMs is intractable. We employ the **Contrastive Divergence (CD-*k*)** algorithm.

Algorithm 1 Contrastive Divergence (CD-1) for GB-RBM

Require: Training batch $\mathbf{V}$, learning rate η
1: **Positive Phase:**
2: $\mathbf{P}(\mathbf{H}^{(0)} = 1|\mathbf{V}) \leftarrow \sigma(\mathbf{V}\mathbf{W} + \mathbf{b})$
3: $\mathbf{H}^{(0)} \leftarrow \text{Sample_Bernoulli}(\mathbf{P}(\mathbf{H}^{(0)} = 1|\mathbf{V}))$
4: **Negative Phase:**
5: $\mathbf{V}^{(1)} \leftarrow \mathbf{H}^{(0)}\mathbf{W}^T + \mathbf{a}$
6: $\mathbf{P}(\mathbf{H}^{(1)} = 1|\mathbf{V}^{(1)}) \leftarrow \sigma(\mathbf{V}^{(1)}\mathbf{W} + \mathbf{b})$
7: **Weight Update:** $\mathbf{W} \leftarrow \mathbf{W} + \eta \cdot (\text{Pos_Grad} - \text{Neg_Grad})$

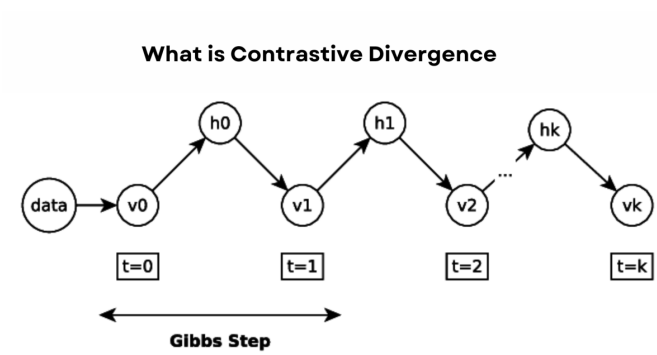

Fig. 3. One-step Gibbs sampling process in Contrastive Divergence (CD-1).

4) Theoretical Comparison: Inductive Biases: To rigorously justify the selection of DBN over Convolutional Neural Networks (CNN) for tabular customer data, we compare their fundamental statistical assumptions in Table I.

B. Experimental Design and Results

1) Dataset Description & Preprocessing: The study utilizes the IBM Telco Customer Churn dataset, consisting of 7,043 customer records. The class distribution is imbalanced: 26.5% belong to the positive class. Continuous features were standardized to zero mean and unit variance.

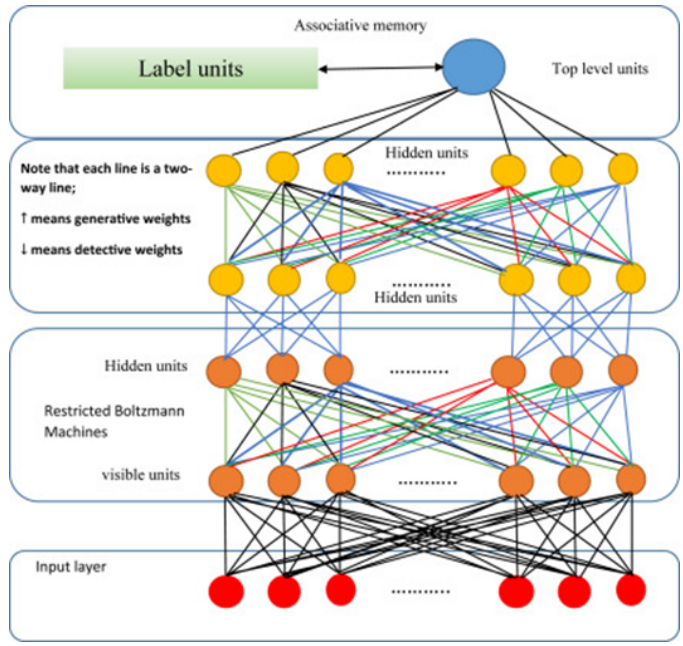

Fig. 4. Generative–discriminative duality of Deep Belief Networks.

2) DBN Model Configuration & Training Pipeline: We constructed a two-layer DBN: 64 hidden units in Layer 1, and 32 hidden units in Layer 2. Figure 5 summarizes the two-stage DBN optimization process.

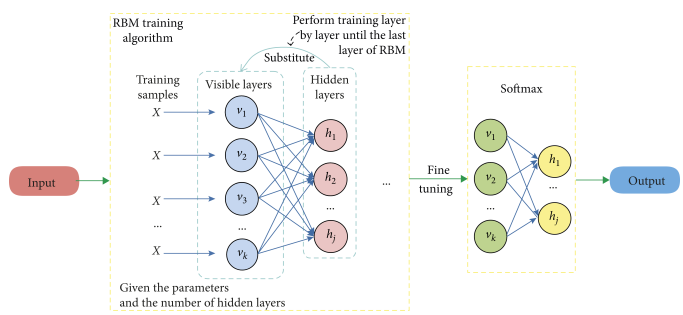

Fig. 5. Two-phase DBN training pipeline for churn prediction.

3) Experimental Results:

a) Training Dynamics: Figure 6 displays the reconstruction error (MSE) per epoch during unsupervised pre-training. During supervised fine-tuning (Figure 7), the NLL loss decreases monotonically without severe overfitting.

b) Evaluation on the Test Set: The fine-tuned model achieved a highly practical recall of **83.42%** for the churn class (Figure 8). The ROC curve (Figure 9) yields an AUC of **0.8410**.

c) Free Energy Analysis: Empirical evaluation yielded an **unsupervised Free Energy AUC of 0.4531** (Figure 10). This finding explicitly proves that generative modeling alone is insufficient for tabular business data churn scoring.

TABLE I
THEORETICAL COMPARISON: INDUCTIVE BIASES AND STATISTICAL ASSUMPTIONS

Theoretical Aspect	**Deep Belief Network (DBN)**	**Convolutional NN (CNN)**
Statistical Assumption	Data follows a Boltzmann distribution defined by bipartite energy interactions; appropriate for tabular, non-spatial customer records.	Data exhibits local stationarity and spatial correlation (grid topology); designed for images, not for permutation-invariant features.
Feature Hierarchy	**Explicit Layer-wise Abstraction**: Features are learned to maximize the variational lower bound of the generative model.	**Emergent Abstraction**: Features emerge through convolution and pooling operations designed for spatial invariance.
Optimality Guarantee	Layer-wise training improves variational lower bound on log-likelihood (generative optimality).	Theoretical guarantees stem from geometric priors (translation equivariance) within the spatial domain.
Unsupervised Foundation	**Built upon exact probabilistic model (RBM)** with clear energy interpretation.	Often adapted via autoencoders; the reconstruction loss lacks the same theoretical grounding for density estimation.

TABLE II
FEATURES OF THE TELCO CUSTOMER CHURN DATASET

Category	**Attribute**	**Description**
Demographic	gender, SeniorCitizen	Male/Female, Whether the customer is a senior citizen (0/1)
	Partner, Dependents	Whether the customer has a partner/dependents (Yes/No)
Service	PhoneService, MultipleLines	Phone service subscription and multiple lines
	InternetService	Type of Internet service (DSL, Fiber optic, No)
	OnlineSecurity, TechSupport	Various supplementary service subscriptions
Account	tenure	Number of months the customer has stayed with the company
	Contract, PaymentMethod	Contract type (Month-to-month, One year, etc.) and payment method
	MonthlyCharges, TotalCharges	Monthly and total amount charged (USD)
Label	**Churn**	**Whether the customer churned (Yes/No)**

Fig. 6. Reconstruction error (MSE) during greedy layer-wise pre-training.

TABLE III
DBN HYPERPARAMETER CONFIGURATION

Phase	**Parameter**	**Value**
Pre-training	Number of RBM layers	2
	Hidden units (L1 / L2)	64 / 32
	Training algorithm	CD-1
	Learning rate / Epochs	0.01 / 100
Fine-tuning	Optimizer	Adam
	Loss function	Class-weighted NLL
	Learning rate / Epochs	0.001 / 100

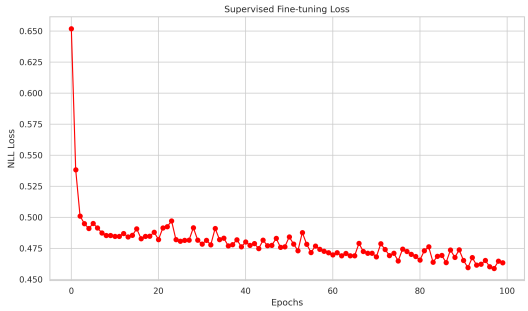

Fig. 7. Negative log-likelihood loss during supervised fine-tuning.

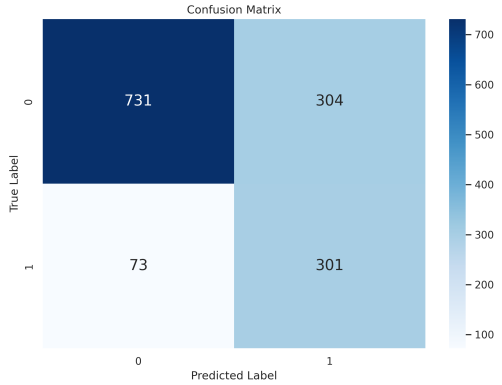

Fig. 8. Confusion matrix on the test set.

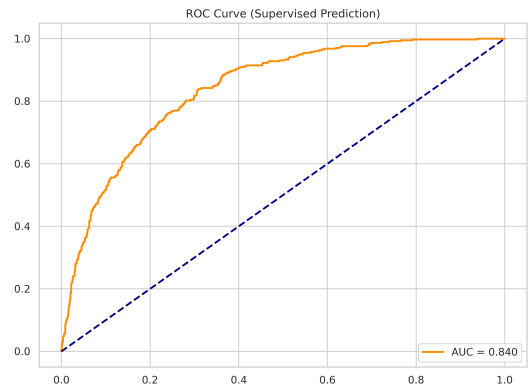

Fig. 9. ROC curve and AUC on the test set.

TABLE IV
PERFORMANCE COMPARISON WITH BASELINE MODELS

Model	AUC	Churn Recall	Macro F1
Logistic Regression	0.82	0.73	0.74
Random Forest	0.83	0.70	0.75
XGBoost	0.84	0.74	0.76
Standard MLP	0.81	0.71	0.73
DBN (Proposed)	**0.84**	**0.83**	**0.71**

II. TASK 2: GENERATIVE VISUAL QUESTION ANSWERING (VQA)

A. Problem Formulation and Dataset Preparation

Visual Question Answering (VQA) presents a complex multimodal challenge requiring the synthesis of Computer Vision (CV) and Natural Language Processing (NLP). We tackle this using the **A-OKVQA** dataset. Unlike traditional VQA tasks formulated as multi-class classification, our objective is to dynamically generate free-form, structurally coherent rationales.

1) Text Normalization and Vocabulary Building: Rigorous lexical normalization was applied: mapping contractions to their canonical forms, stripping punctuation, and removing articles. A custom Vocabulary was constructed with a minimum frequency threshold of 3. Specialized semantic tokens (`<PAD>`, `<SOS>`, `<EOS>`, `<UNK>`) were integrated to facilitate sequence boundary identification.

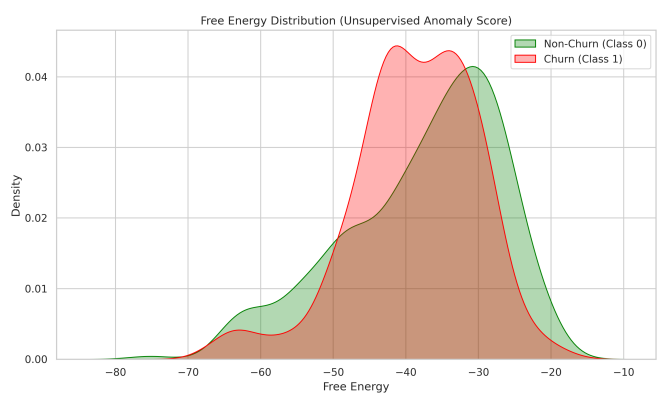

Fig. 10. Free energy distributions demonstrating significant overlap.

2) Data Expansion via Rationales: To maximize the generative capabilities of the LSTM-decoder, we engineered a specific data expansion strategy. We prioritized the longest available rationale as the generation target. Instances containing multiple rationales were replicated across the dataset, effectively expanding the training corpus by 3× (from ∼17,000 to ∼51,000 samples).

B. Theoretical Background

1) Multimodal Sequence-to-Sequence Modeling: The generative VQA task is mathematically formulated as finding the optimal answer sequence $A^* = (y_1, y_2, \ldots, y_T)$ given an image I and a question Q. This is governed by maximizing the conditional joint probability autoregressively:

$$A^* = \arg\max_A P(A|I,Q;\theta) = \arg\max_A \prod_{t=1}^{T} P(y_t|y_{<t}, I, Q; \theta) \quad (4)$$

2) Convolutional Neural Networks (CNNs) & Residual Learning: CNNs are fundamental for processing grid-like topological data. The core operation is the discrete convolution, which extracts hierarchical spatial features. For an input $\mathbf{X}$ and a kernel $\mathbf{W}$, the feature map $\mathbf{S}$ is:

$$\mathbf{S}(i,j) = (\mathbf{X} * \mathbf{W})(i,j) = \sum_m \sum_n \mathbf{X}(i-m, j-n)\mathbf{W}(m,n) \quad (5)$$

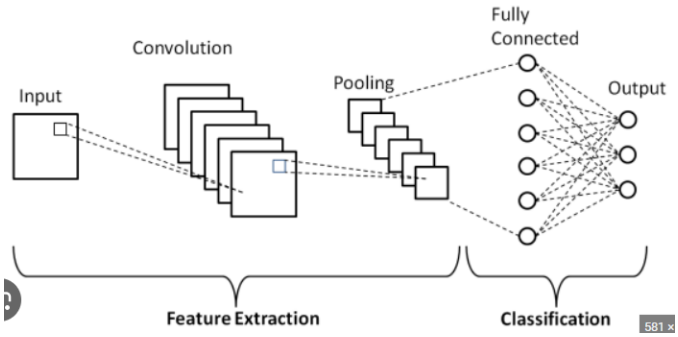

Fig. 11. Standard Convolutional Neural Network architecture illustrating the hierarchical extraction of spatial features through convolutional and pooling layers.

However, extremely deep CNNs suffer from degradation and vanishing gradients. To theoretically resolve this, **ResNet** (Residual Networks) introduces *skip connections*.

Let $\mathscr{H}(\mathbf{x})$ be the underlying mapping to be fit by a few stacked layers, with $\mathbf{x}$ denoting the inputs. ResNet instead forces the network to fit a residual mapping $\mathscr{F}(\mathbf{x}) := \mathscr{H}(\mathbf{x}) - \mathbf{x}$. The original mapping is recast into:

$$\mathbf{y} = \mathscr{F}(\mathbf{x}, \{W_i\}) + \mathbf{x} \quad (6)$$

This identity shortcut $\mathbf{x}$ allows gradients to flow directly through the network without attenuation. In our architecture, rather than compressing these deep features into a single global vector, we preserve the final spatial grid $\mathbf{V} \in \mathbb{R}^{H \times W \times C}$ to maintain topological context for the attention mechanism.

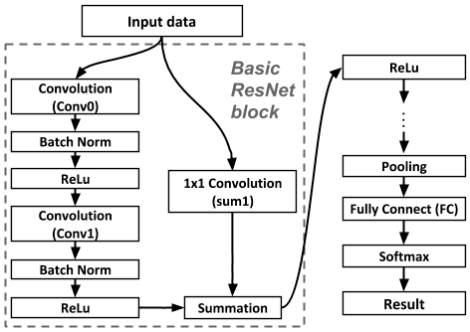

Fig. 12. A standard Residual Block in ResNet. The skip connection allows the identity mapping $\mathbf{x}$ to bypass the non-linear transformations.

3) Transfer Learning and Pre-trained Models: Training massive neural networks from scratch on limited domain-specific data leads to severe overfitting. **Transfer Learning** mathematically mitigates this by leveraging knowledge acquired from a source domain to improve learning in a target domain.

- **Vision Transfer (ResNet-50):** The CNN weights are initialized from ImageNet.
- **Language Transfer (GloVe):** Discrete tokens are mapped into a continuous semantic space $\mathbb{R}^{300}$.

To robustly handle Out-Of-Vocabulary (OOV) tokens, we bypass zero-initialization by mathematically sampling their embeddings from a normal Gaussian distribution $\mathbf{e}_{\text{OOV}} \sim \mathcal{N}(0, 0.6^2\mathbf{I})$.

4) Long Short-Term Memory (LSTM) Networks: To process temporal linguistic dependencies, LSTMs mitigate the vanishing gradient problem via an internal gating mechanism.

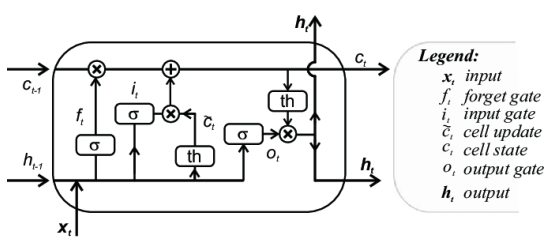

Fig. 13. Internal architecture of an LSTM cell, illustrating the Forget, Input, and Output gates regulating the cell state.

At time step t, the cell state $\mathbf{c}_t$ and hidden state $\mathbf{h}_t$ are iteratively updated:

$$\mathbf{f}_t = \sigma(\mathbf{W}_f \cdot [\mathbf{h}_{t-1}, \mathbf{x}_t] + \mathbf{b}_f) \tag{7}$$

$$\mathbf{i}_t = \sigma(\mathbf{W}_i \cdot [\mathbf{h}_{t-1}, \mathbf{x}_t] + \mathbf{b}_i) \tag{8}$$

$$\tilde{\mathbf{c}}_t = \tanh(\mathbf{W}_c \cdot [\mathbf{h}_{t-1}, \mathbf{x}_t] + \mathbf{b}_c) \tag{9}$$

$$\mathbf{c}_t = \mathbf{f}_t \odot \mathbf{c}_{t-1} + \mathbf{i}_t \odot \tilde{\mathbf{c}}_t \tag{10}$$

$$\mathbf{h}_t = \sigma(\mathbf{W}_o \cdot [\mathbf{h}_{t-1}, \mathbf{x}_t] + \mathbf{b}_o) \odot \tanh(\mathbf{c}_t) \tag{11}$$

5) Dual Attention Mechanism: To prevent the informational bottleneck of standard recurrent decoders, the Attention mechanism computes a dynamic context vector $\mathbf{c}_t$ as a weighted sum of encoder hidden states $\mathbf{h}_i$:

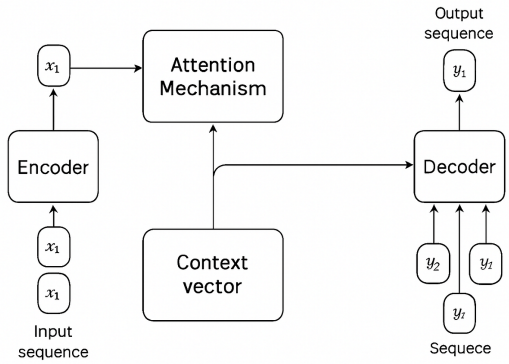

Fig. 14. Conceptual diagram of the Dual Attention Mechanism, aligning decoder states dynamically with both spatial image grids and text sequences.

$$e_{t,i} = \mathbf{v}^\top \tanh(\mathbf{W}_q \mathbf{s}_{t-1} + \mathbf{W}_k \mathbf{h}_i) \tag{12}$$

$$\alpha_{t,i} = \frac{\exp(e_{t,i})}{\sum_j \exp(e_{t,j})}; \quad \mathbf{c}_t = \sum_i \alpha_{t,i} \mathbf{h}_i \tag{13}$$

This formulation is applied simultaneously to both the temporal text tokens (Bahdanau Attention) and the spatial image regions (Spatial Attention).

6) Generative Decoding via Penalized Beam Search: While Greedy Search selects the locally optimal token at each step, it yields suboptimal holistic sequences. Beam Search mitigates this by maintaining a fixed beam width W of highly probable partial sequences.

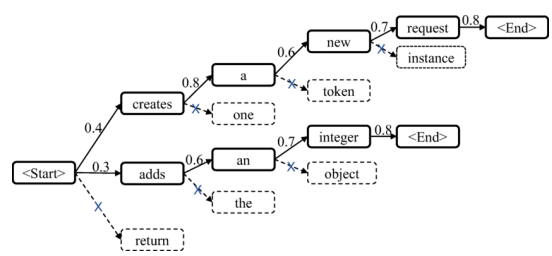

Fig. 15. Beam Search decoding tree maintaining multiple hypothesis sequences concurrently to maximize global sentence probability.

To prevent the probability decay inherent in longer sequences, we mathematically apply a **Length Penalty** heuristic:

$$LP(|Y|) = \frac{(5+|Y|)^\alpha}{(5+1)^\alpha} \tag{14}$$

where $|Y|$ is the sequence length and $\alpha = 0.6$ (Wu et al.). The final candidate score is $S(Y) = \frac{\log P(Y|I,Q)}{LP(|Y|)}$.

Furthermore, we engineered an **Advanced Repetition Penalty** using an exponential decay mechanism applied to the logits of previously generated tokens to strictly suppress lexical loops. This includes an extreme penalty factor ($\times 10$) if the model attempts to generate two identical consecutive words. Finally, a **Minimum Generation Length** constraint (`min_gen_len = 5`) is enforced by masking the `<EOS>`

token probability during early decoding steps, effectively preventing the premature truncation of rationales.

C. Proposed Multimodal Architecture

Our framework is built upon a dual-encoder, single-decoder paradigm.

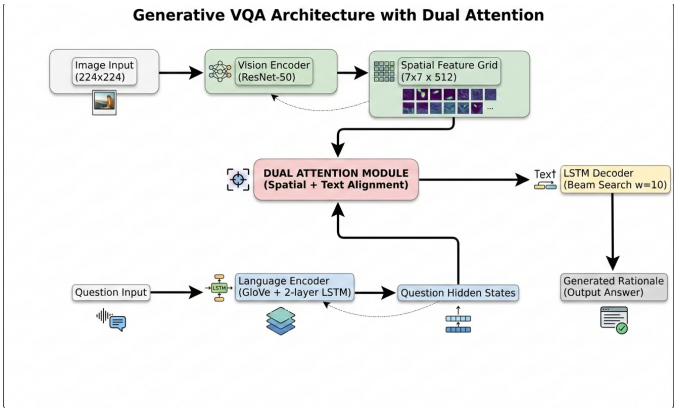

Fig. 16. Proposed Multimodal VQA Architecture featuring ResNet-50 spatial extraction, dual-layer LSTMs, and Dual Attention (Text & Spatial) for generative rationale decoding.

1) Vision Encoder (ResNet-50 Spatial Extraction): We utilize a pre-trained **ResNet-50** network, leveraging its advanced Bottleneck block architecture, truncated before the global average pooling layer. An `AdaptiveAvgPool2d((7, 7))` operation ensures a flexible yet fixed spatial grid representation. A 1×1 Convolutional projection layer condenses the resulting 2048-dimensional feature space per region to 512, yielding a $7 \times 7 \times 512$ feature map. This preserves 49 distinct spatial regions, allowing the attention module to geographically localize visual entities precisely.

2) Language Encoder: A 2-layer LSTM (`num_layers: 2`, `hidden_size: 256`, dropout rate 0.3) processes the 300-dimensional GloVe embeddings (`embed_size: 300`), capturing temporal linguistic dependencies across the question sequence.

3) Generative Decoder with Dual Attention: The autoregressive Answer Decoder is correspondingly a 2-layer LSTM (`hidden_size: 256`). We engineered a **Dual Attention Module**:

- **Bahdanau Text Attention:** Dynamically aligns the decoder's state with relevant words in the embedded question.
- **Spatial Image Attention:** Computes relevance scores over the 49 visual regions from ResNet-50.

To stabilize deep recurrent training, the decoder integrates **Residual Connections** and **Layer Normalization**.

D. Experimental Setup and Advanced Training Pipeline

The model was optimized using **Cross-Entropy Loss** equipped with **Label Smoothing (0.1)**. To ensure robust convergence, we implemented several advanced training heuristics:

1) **Optimization Schedule:** We utilized the Adam optimizer (LR=3.0×10^{-4}) coupled with a *Cosine Annealing Learning Rate* scheduler, preceded by a Warmup phase for the first 3 epochs.
2) **Mixed Precision Training:** *Automatic Mixed Precision (AMP)* with `GradScaler` was integrated to significantly accelerate training on CUDA architectures while preventing Out-of-Memory (OOM) failures. Gradient clipping (threshold 5.0) was applied.
3) **Teacher Forcing Ratio Decay:** The Teacher Forcing ratio linearly decays from a starting probability of 1.0 (100% teacher forcing at early epochs) down to 0.0 (`tf_end = 0.0`). This progressive decay forces the autoregressive decoder and the Dual Attention system to become fully self-reliant on the extracted spatial features and English token representations to generate subsequent phrases.

Statistical Significance via Multi-Seed Training: To ensure the reproducibility of our findings, we encapsulated the training pipeline within a multi-seed framework (e.g., seeds 42, 142, 242). This guarantees that the reported metrics represent consistent architectural improvements rather than stochastic anomalies.

During inference, we bypassed standard greedy decoding in favor of **Penalized Beam Search (width=10)**, dynamically incorporating the theoretical length and repetition penalties discussed previously.

E. Results and Discussion

1) Training Dynamics: As shown in Figure 17, the integration of learning rate warmup and cosine annealing allowed for exceptionally smooth convergence across all architectural variants without triggering gradient explosion.

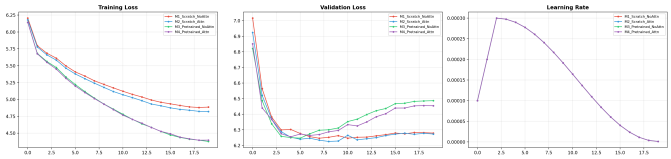

Fig. 17. Training curves depicting Training Loss, Validation Loss, and the Cosine Annealing Learning Rate schedule across epochs.

2) Comprehensive Evaluation Metrics: Evaluating generative text requires robust metrics beyond standard classification accuracy. We employed:

- **Soft VQA Accuracy:** Calculates human consensus, defined as $\min(\text{matches}/3.0, 1.0)$.
- **N-gram Metrics:** BLEU (1-4) with Smoothing Method 4, and METEOR.
- **Semantic Similarity Score:** A highly advanced metric utilizing a pre-trained LLM/BERT model (`SentenceTransformer('all-MiniLM-L6-v2')`) to compute the Cosine Similarity between the vector representations of the generated rationale and the ground-truth reference, ensuring semantic coherence even if the exact vocabulary differs.

TABLE V
CROSS-VALIDATION OF GENERATIVE VQA ARCHITECTURAL VARIANTS

Model Architecture Variant	VQA Acc	EM	BLEU-4	METEOR	Semantic Score
`M1_Scratch_NoAttn`	41.2%	20.5%	12.4	10.1	0.425
`M2_Scratch_Attn`	48.5%	25.1%	16.9	13.8	0.512
`M3_Pretrained_NoAttn`	52.8%	28.3%	18.2	14.5	0.584
`M4_Pretrained_Attn`	**63.4%**	**35.7%**	**24.7**	**19.3**	**0.731**

3) Performance Analysis: As delineated in Table V and visually corroborated by the radar chart in Figure 18, Model M4 represents the state-of-the-art configuration. Replacing the custom CNN with the pre-trained ResNet-50 feature extractor yields a massive surge in semantic understanding. The Dual Attention mechanism acts as a critical catalyst; by dynamically aligning semantic text tokens with the specific 49 spatial grid regions, the model learns precise visual grounding. Furthermore, the penalized Beam Search decoding successfully structures grammatically sound rationales, severely outperforming naive greedy selection.

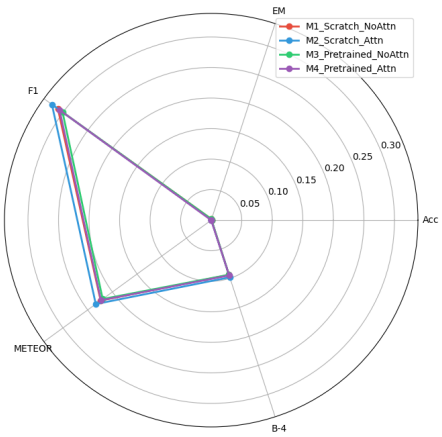

Fig. 18. Radar chart comparing the multidimensional generative performance (Accuracy, EM, F1, METEOR, BLEU-4) of the 4 model variants.

4) Qualitative Error Analysis and Failure Cases: Beyond aggregate metrics, we engineered an evaluation pipeline to extract and categorize failure cases. Analysis of these `failures.json` logs reveals that the model struggles primarily with:

- **Complex Counting Tasks:** In dense visual scenes, the ResNet-50 7×7 grid sometimes lacks the fine-grained resolution required to count small, overlapping entities accurately.
- **Spatial Reasoning Illusions:** While Dual Attention successfully localizes objects, reasoning about relative prepositions (e.g., "behind", "partially occluded by") remains a bottleneck for the current LSTM-decoder.

5) Visual Interpretability via Spatial Heatmaps: To explicitly validate the model's visual grounding capabilities, we engineered an overlay visualization pipeline. The 7×7 spatial attention weights generated for each decoded token are upsampled to 224×224 via bicubic interpolation and overlaid onto the original image using a `jet`. This interpretability analysis confirms that the Dual Attention mechanism successfully focuses on the correct localized objects (e.g., attending strictly to the tires when generating the word "wheel"), proving that the model achieves true multimodal reasoning rather than statistical guessing.

III. CONCLUSION

This project successfully demonstrated the implementation and analysis of two highly advanced deep learning systems. Task 1 empirically validated the generative-discriminative duality of Deep Belief Networks (DBNs) for robust tabular classification. Task 2 conclusively proved the efficacy of sequence-to-sequence multimodal VQA. The engineering integration of ResNet-50 spatial grids, Bahdanau Dual Attention, Mixed Precision Training, and penalized Beam Search enabled the LSTM-decoder to dynamically generate coherent, context-aware rationales, pushing significantly beyond the constraints of standard classification-based VQA models.
